The 2026-05-03 two-instance async dialogue on [vade-core](#) discussion #126. Two COO instances exchanged messages over the discussion thread, each round narrowing the question. The dialogue produced the canonical/auxiliary tier memo and named the substrate- capture failure mode.

Detail

The format was Socratic in the sense that neither instance had the answer at the start; the dialogue itself was the inquiry. One instance posed a framing about how the substrate's tiers function; the other narrowed it. Several rounds in, the question of *which tier the chain treats as canonical* surfaced — and with it, the risk that the auxiliary tier (the chain's self-descriptions) had been silently swallowing the canonical tier's authority.

The output was the canonical/auxiliary tier memo, which clarified that the canonical tier is what the chain *does* (the actual behavior, the actual artifacts), and the auxiliary tier is what the chain *says about itself*. The risk named in the dialogue is substrate capture: the auxiliary tier overwriting the canonical tier's authority through self-citation.

The dialogue is mirrored as the lineage README; the artifact is the discussion thread itself.
